

(LFU Cache)

Prerequisite to understand LFU cache is that you know LRU cache → what Striver's video for this. or just read the explanation that you coded up yourself.

Diagrammatic View of how to design LRU cache.

In LRU cache, you have to remove the least Recently Used value from the cache in case eviction is required

~~**~~ LRU cache, remember, (Doubly Linked List + HashMAP) → (LRU Cache)

Node { int k;
int v;
Node prev, next;

This is the initialization of LRU cache.

(P.T.O)

put (k,v) Node = newNode (k,v).

insertNode (head, head.next, newNode)

map (key \rightarrow Node)

\hookrightarrow whenever a get (key) is called, you pick up the node from hashmap

(Step 1) remove the node from the DLL.

(Step 2) Insert it after head making it the most recently used. In case of put do the similar.

Not drawing the diagram here

Now we will use this to build LFU cache.

I was planning to have, \Rightarrow (my thought process)

$\text{Map}(\text{Integer}, \text{Integer}) \rightarrow$ Key to frequency Map

$\text{Map}(\text{Integer}, \text{LRUCache}) \rightarrow$ frequency to LRU cache implementation.

4)

Now I was

trying to implement this LRU cache again and for each frequency I would do

$\text{mp-computedIfAbsent}(\text{freq}, (\text{Integer}, \text{key}) \rightarrow \text{new}(\text{LRUCache}))$

But this implementation is very tough and time consuming

So then I saw the editorial and came across this

LinkedHashSet and LinkedHashMap, which can simulate this LRU behavior, since they preserve the order of insertion.

$\text{new LinkedHashMap}() (\text{capacity}, \text{lf}, \text{true})$

\downarrow
accessOrder

\downarrow
converts it into total LRU,

P.T-C

Basically

the key which you accessed right now is moved to the end.

But we won't be using LinkedHashMap, instead we will use LinkedHashMap

and ~~we~~ try to make it behave like LRU.

LRU \rightarrow {
LinkedHashSet.remove(key)
LinkedHashSet.add(key)
~~LinkedHashSet~~ int broKey = linkedHashSet.iterator().next();
LinkedHashSet.remove(broKey);
} \downarrow 1st key

So we will utilize the above behavior.

Map<Integer, Integer>

Map<Integer, LinkedHashSet<Integer>>

~~min~~ minFreq = 0.

Pot call

We need minFreq and not maxFreq because for eviction, we need to pop the key with least frequency

So when a pot happens, pot(k, v)

Step 1 \rightarrow get previous frequency of k, = prevFreq

Step 2 \rightarrow Remove key from the LinkedHashSet of prevFreq

Step 3 \rightarrow newFreq \rightarrow prevFreq + 1

Step 4 \rightarrow insert k into the LinkedHashSet of newFreq

Step 5 \rightarrow ~~check~~ ~~maxFreq~~ ~~newFreq~~ then update
{update minFreq if required} ~~maxFreq = newFreq~~

Get Call

When a get call happens, \rightarrow

Simply get the value from the
 $\text{map}(\text{Integer}, \text{Integer}) \rightarrow$ oh wait you need to store the
value along with frequency as
well.

$\text{Map}(\text{Integer}, \text{Node}) \rightarrow \text{get}(\text{key}).\text{value};$

$\text{Node} \{$
 freq
 $\text{value};$
 $\}$

then just trigger a

$\text{put}(\text{key}, \text{value})$

this will take care of
incrementing the frequency of
the key automatically

See, code to understand properly. Practice writing the code properly.

~~min~~ Freq confusion, \rightarrow the thing is in steps of put, I did
not clarify how to update minFreq .

update $\text{minFreq} \rightarrow$

All we are doing $\text{newFreq} = \text{prevFreq} + 1$,

and popping the key from prevFreq ,

check if any key is present in minFreq .

if no key with $\text{freq} = \text{minFreq}$ { no key in LinkedHashSet of minFreq }

then $\text{minFreq} = \text{newFreq}$.

Since no $\text{remove}()$ operation so $\text{minFreq}--$, never happens.

Sheesh! That was a long explanation.

But wait, there is a more intuitive way to implement LFU cache while solving a problem. All $O(1)$ data structures,

I was trying to do that using the LinkedHashSet and `map(Integer, Integer)` but did not work, so what worked?

Doubly LinkedList and having LinkedHashSet inside each node

put
get (all comes)

→ `map<Integer, Node>` → Just like LFU cache, you directly get the node
Step 1 →

Step 2 → remove the key from that node's LinkedHashSet.

Step 3 → check if LinkedHashSet is empty now after this removal, if empty then remove the node from DLL.

remove (node) {
 `node1 = node.prev`
 `node2 = node.next`
 `node.prev = null`
 `node.next = null`
} → Link these two nodes
 `node1.next = node2`
 `node2.prev = node1`

Step 4 you got the prevFreq. from the node,

$$\text{newFreq} = \text{prevFreq} + 1$$

check if $(\text{node} \rightarrow \text{next} \rightarrow \text{freq}) == \text{newFreq}$

next node has
 $\text{freq} = \text{newFreq}$

HashKey free,
insert key into the
linked Hashset of
nextNode

Create a new Node

with $\text{freq} = \text{newFreq}$
and this key in the

linked Hashset of that
key.

insertNode

b/w

↓ node and node-next

update the
location of the key

$\text{mp} \rightarrow \text{put}(\text{key}, \text{node where you inserted the key})$.

getCall → get the value
from list say another map has $\text{key} \rightarrow \text{value}$ entry
and then do a put call with same key, value,
this takes care of increasing frequency of the
key

Advantages of this approach → ① don't have to specifically maintain minFreq
you know head-next is the minFreqNode.

② this allows you to support decrement of frequency of key as well.

③ intuitive and similar to LRU cache
